Abstract

Holocene paleo-mean sea levels are estimated from the geometry and elevation of emerged marine notches and coral reef terraces along the coastlines of the Philippine Islands. Two hundred forty-six representative sites, scattered almost all around the Philippines, were chosen for profiling. Age control is provided by fifty-six radiocarbon dates and fifty alpha spectrometric $^{230}\text{Th}/^{234}\text{U}$ dates. The notches and terraces, with the oldest dating back to approximately 9.19 ± 0.28 ky, have elevations ranging from 0.1 to 6.7m above the present mean sea level. Adjacent coastal areas show different paleo-sea level histories in both the level and number of relative stillstands due to local faulting. Discrete double notches suggest the possible occurrence of two emergent stillstands, with the older at a lower elevation. Possible across-site variation in the duration and timing of initiation and termination of these stillstands can be due to differences in regional tectonics and crustal response to hydro-isostasy, or an artifact of sampling.

Key words: age, coral reef terraces, Holocene, notches, Philippine

Introduction

Notches and coral reef terraces formed during the Holocene can be observed along many Philippine coasts. Since 1998 the authors have used these coastal features to reconstruct sea level changes in the Philippine Islands (Figure 1). Age control for the timing of sea level changes consists of fifty-six radiocarbon and fifty $^{230}\text{Th}/^{234}\text{U}$ dates.

The results of the study have been presented in several conferences and published in scientific journals (e.g. Maeda et al., 1997, 1999a–c, 2001, 2002, 2003; Berdin et al., 2000, 2001, 2003; Siringan et al., 2000). Perhaps, the most significant finding of the study is the documentation of two high stands of sea level in the mid-Holocene. However, much of the data from these studies have not been published due to limitations of

space imposed on publications. These data are valuable to sea level researchers and accordingly we publish them here.

This paper contains the following data concerning notches and coral reef terraces geographical location (Table 1), coastal profiles and relevant photographs (Plates 1–58), sample elevation and radiocarbon and radiochemical isotope ages (Tables 1–4).

Methods

Notches and coral reef terraces were examined, whenever possible, at low tide. These profiles are established in representative sites using a hand or automatic level and the elevations are adjusted to the present mean sea level based on predicted tide heights from the nearest tide stations. Data for mean sea

levels of the stations used as reference in this paper are presented in Table 2. Comparison of data from multiple surveys and wave conditions indicate errors within $\pm 0.15\text{m}$.

Surveyed sites were located on 1:50,000 topographic maps with the aid of a hand-held GPS; Global Positioning-Satellite.

For age control, coral and oyster shell samples were dated using ^{14}C at Nagoya University and at the Beta Analytic Laboratory and $^{230}\text{Th}/^{234}\text{U}$ at Kanazawa University.

Radiocarbon ages were calibrated using the program of Stuiver and Reimer (1993) and t in Stuiver et al. (1998).

Marine notches are indentations in coastal rocks, a few centimeters to several meters deep, that are formed through dissolution and bioerosion, especially in limestone (Pirazzoli, 1986). Different types are classified according to tidal levels and site exposure, but the most common and the most useful sea-level indicator is the tidal notch, a recumbent V- or U-shape that develops within the intertidal zone along a relatively sheltered coast. Retreat points, the indented parts of notches, form near mean sea level and hence are used to estimate paleo-shorelines in emerged or submerged coasts. The floor and the roof, respectively, approximate the lowest and the highest tidal levels; the vertical distance between the edges of these features defines the height of the notch and thus is used to estimate the mean tidal range while the notch was undergoing formation. In notches with relatively intact roofs, the horizontal distance between retreat points and roof edges, termed the depth of the notch, is used to estimate stillstand duration.

Greater wave action shifts the roof and the retreat point upwards. Where water turbulence increases, organic incrustations may develop on the floor of the notch.

Acknowledgements

Our sincere gratitude goes to several persons who have helped us during the course of this work. We would like to thank the following for their assistance on and off the field—Rose Berdin, Gerald Quina, Peter Zamor and Napoleon Villanueva of the University of the Philippines, Miguel C. Cano of the St. Stephen's High School, Prof. Toshio Kawana of the University of the Ryukyus, Prof. Hiroshi Sato of Himeji Institute of Technology, Dr. Keiichi Sasaki of Kanazawa Gakuin University and

Mr. Akira Fukuchi of Okayama University. Likewise, invaluable assistance for age dating was provided by Prof. Akio Omura, Mr. Yosuke Hosono and Mr. Shin Atsumi of Kanazawa University, and Prof. Toshio Nakamura of Nagoya University. We would like to extend our gratitude to the Toyota Foundation for the research grant and the logistics help from the National Institute of Geological Sciences, University of the Philippines that enabled us to conduct this study.

Plate 1. Marine notches and related features in Samar

Photo 1. Two notches (a and b) are carved along the side of Calowayan Island; the upper notch is etched along the roof of the lower notch (station WSA-4, fig. 200).

Photo 2. This notch relationship is also seen at the adjacent Tinabanan coast (station WSA-2, Fig. 197). Providing age control for the notches are corals and oyster shells. In Tinabanan, corals at 1.0m (d) and 0.7m (e) above mllw, yielded ^{14}C ages of 7255 and 7196 cal BP, respectively.

Photo 3. In a cave on the right of Photo 2(c), an oyster at 2.9m above mllw was ^{14}C dated at 5120 cal BP (Fig. 198).

Photo 4. On the opposite wall, approximately 75m across the embayment from the wall in Photo 2, shells occur along the zone separating the two notches (station WSA-3, Fig. 199). Two samples from 2.9 and one from above 2.8 m above mllw gave ^{14}C ages of 5449, 4180 and 4702 cal BP. In the photo are the authors—Y.M. on the right and F.S. on the left.

Photo 5. The coastal profile of Divinubo Island, located along the east coast of Samar, consists of a wide uplifted coral reef platform paired with two discrete notches (station ESA-6, Fig. 180).

Plate 1

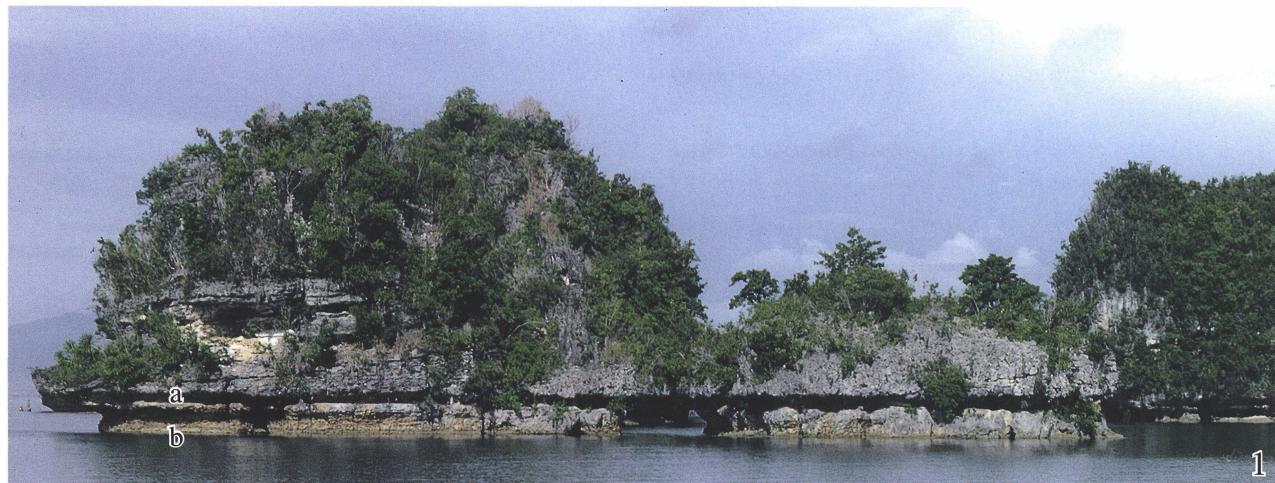

Plate 2. A marine notch and related features in Buyayawon, Southern Samar

Photo 1. The notch (a), 3.3 m above mllw, has a relatively flat floor (station ESA-14, Fig. 189). Below the notch is coral (b) attached to the steep face of the notched wall.

Photo 2. Behind the notched limestone in Photo 1 is a cave where corals (a) are attached to the entrance walls (also see Figs. 188 and 189). The upper limit of the coral (b) is at the same elevation as the notch just outside the cave.

Photo 3. Oyster shells lining the inner walls of the cave have an upper limit of shell concentration at the elevation of the notch.

Photo 4. In an adjacent cave, marked by an arrow (station ESA-15, Fig. 190), an oyster shell taken 3.4 m above mllw yielded a ^{14}C age of 4350 cal BP, whereas 1.1m above mllw gave a ^{14}C age of 7330 cal BP.

Plate 2

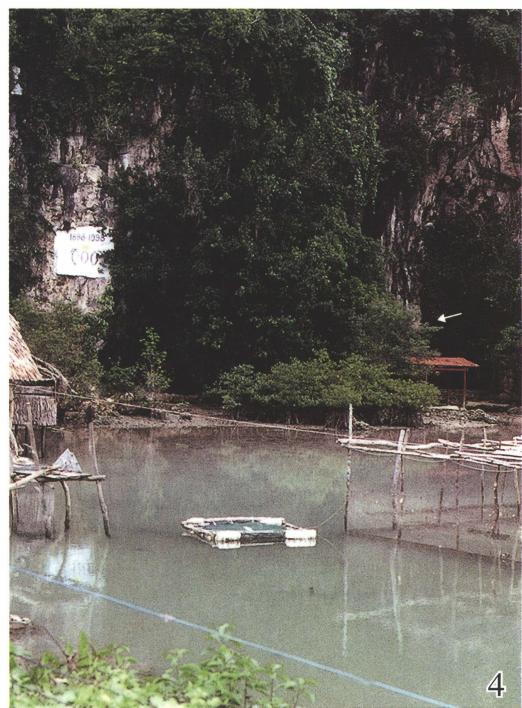

1

2

3

4

Plate 3. Notch and related features in West Samar

Photo 1. (1) and (2) Only one notch, at 1 m above mllw, occurs in Gumiti Island (stations WSA-6 and 7, Figs. 202 and 203). Arrows a and b in Photo 1 point to caves whose walls are lined with oyster shells.

Photo 2. Profile of the notch and the entrance to the first cave (a in Photos 1 and 2).

Photo 3. An oyster, 2.2 m above mllw, from the first cave gave a ^{14}C age of 2160 cal BP.

Photo 4. Oyster shells on the walls of the second cave (b in Photo 1).

Plate 3

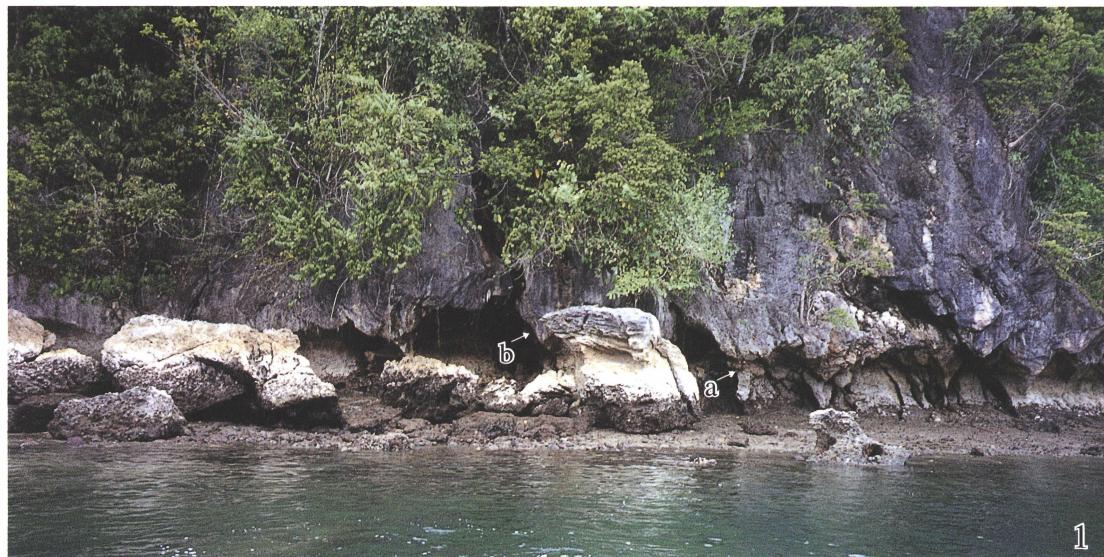

Plate 4. Marine notches and related features in Bacuit Bay, Palawan

Photo 1. Holocene (a) and OIS 5e (b) notches etched on the walls of Miniloc Island (Fig. 212).

Photo 2. *Goniastrea* sp., 0.4 m above mllw, along the floor of the lower notch in Miniloc Island gave a ^{14}C age of 5758 cal BP and a $^{230}\text{Th}/^{234}\text{U}$ age of 5.96 ± 0.22 ky.

Photo 3. Three notches in Lagen Island; the two lower notches, a and b are Holocene and c is correlated to OIS 5e.

Photo 4. A cave in Lagen Island (Fig. 214).

Photo 5. Oysters on the walls of the cave in Photo 4 generally increase in size towards the upper limit of shell occurrence. Four oyster shells, between 1.5 to 1.7 m above mllw, from this cave yielded ^{14}C ages ranging from 3320 to 2594 cal BP.

Photo 6. Three notches are also found in EL Nido Town. The larger, higher notch (a) is assigned an OIS 5e age and the lower two (b and c) are Holocene. A coral (d) at the notch floor, 0.3 m above mllw, was ^{14}C dated 3575 cal BP (Fig. 211).

Plate 4

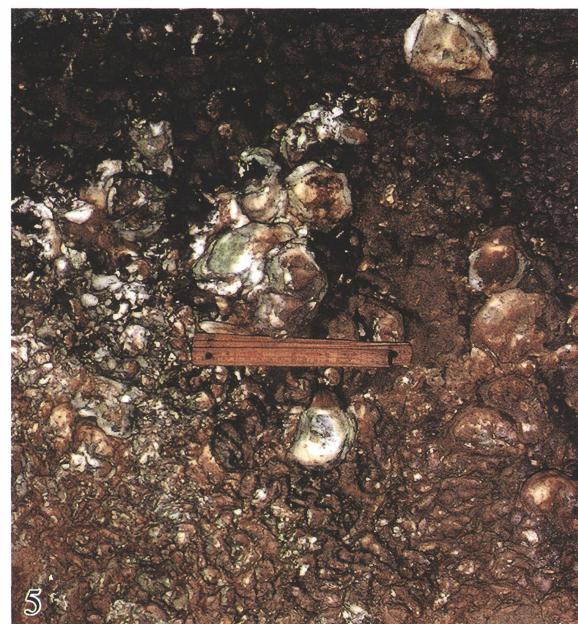

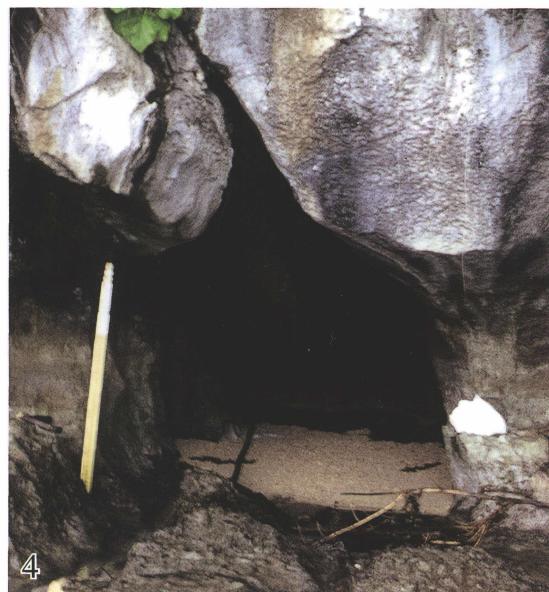

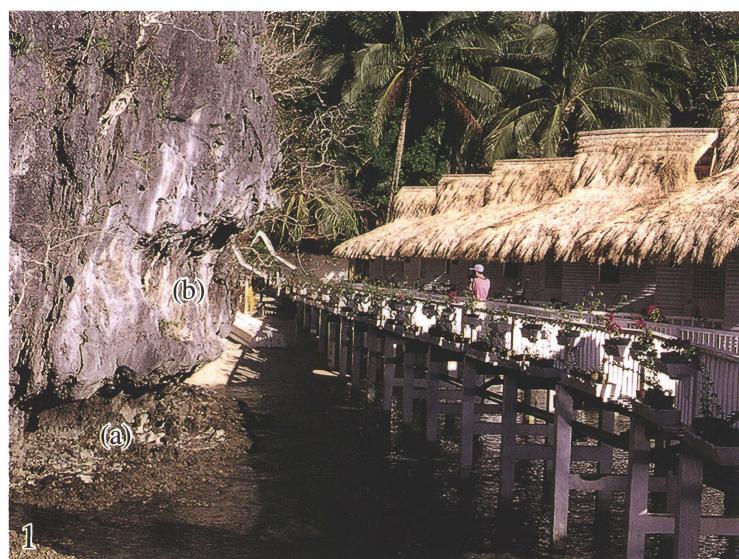

Plate 5. Terraces and notches along the northwest coast of Luzon

Photo 1. The coast at Culili Point is marked by several terraces. In the foreground are four terraces, of possible Holocene ages, at 5.1, 3.0, 2.0 and 1.6 m above mllw (stations ILN-18 and 19, Figs. 22 and 23).

Photo 2. A fairly continuous terrace (a) along the Currimao coast stands at 3.3 to 4 m above mllw (stations ILN-20 to 24, Figs. 24 to 28).

Photo 3. Notches are carved on the scarp of the terrace in Photo 2 (station ILN-22, Fig. 26). A *Goniastrea* sp. from the terrace which is 3.7 m above mllw gave a $^{230}\text{Th}/^{234}\text{U}$ age of 8.20 ± 0.14 ky.

Photo 4. Uplifted *Porites* sp. micro atolls in Paroir, La Union (station LAU-2, Figs. 55-57) are partially submerged during high tide.
